In traditional geometry, affine geometry is considered to be a study between Euclidean geometry and projective geometry. On the one

hand, affine geometry is Euclidean geometry with congruence left out; on the other hand, affine geometry may be obtained from projective geometry by the designation of a particular line or plane to represent the points at infinity.

Description. Projective geometry is less restrictive than either Euclidean geometry or affine geometry. It is an intrinsically non-metrical geometry, meaning that facts are independent of any metric structure. Under the

projective transformations, the incidence structure and the relation of projective harmonic conjugates are preserved. A projective range is the one-dimensional foundation.

Klein's Erlangen program describes geometry as the study of properties invariant under a group of transformations. Affine and projective geometries consider properties such as collinearity of points, and the typical group is the full matrix group. Metric geometries, such as Euclidean geometry

In other words: To each line l of Euclidean geometry, associate some other object $f(l)$, in such a way that $f(l) = f(l')$ if and only if l and l' are parallel. [There are lots of ways to do this. For example, you could let $f(l)$ be the slope of l (a real number, or the symbol "infinity" if l is

Question Corner -- Understanding Projective Geometry

Projective Geometry might be viewed as the geometry of perspective. Two observers of a painting – one looking obliquely, one straight on – will not agree on angles and distances but will both see lines as lines and will agree on whether they meet. So projective transformations (such as relate the two observers' views) are less rigid than Euclidean, or even affine, transformations.

Conversely, any affine linear transformation extends uniquely to a projective linear transformation, so the affine group is a subgroup of the projective group. For instance, Möbius transformations (transformations of the complex projective line, or Riemann sphere) are affine (transformations of the complex plane) if and only if they fix the point at infinity .

Also illuminating is the treatment of affine
and Euclidean geometry, which are introduced
as specialisations of projective geometry. By
singling out a plane at infinity (so you can
define parallels) you get affine geometry;
then by specifying within this a particular
polarity you get a definition of right
angles, and from that the Euclidean angle and

Projective Geometry: Amazon.co.uk: Coxeter, H.S.M . . .

In Euclidean geometry, constructions are made with ruler and compass. Projective geometry is simpler: its constructions require only a ruler. In projective geometry one never measures anything, instead, one relates one set of points to another by a projectivity. The first two chapters of this book introduce the important concepts of the subject and provide the logical foundations.

Projective connection In differential geometry, a projective connection is a type of Cartan connection on a differentiable manifold. The structure of a projective connection is modeled on the geometry of projective space, rather than the affine space corresponding to an affine connection.
